Niall Madden (Niall.Madden@NUIGalway.ie)

# Week 8: Linear Systems, and Operator Overloading

9am, 30 March, and 4pm, 31 March, 2021

- 1 Part 1: Solving Linear Systems (again)
  - Jacobi's method
  - Implementation
- 2 Part 2: A matrix class
  - MatVec
- 3 Part 3: Coding Jacobi's method
- 4 Part 4: Copy Constructors
  - A new constructor
- 5 Part 5: Operator Overloading
  - Eg 1: Adding two vectors
- 6 Part 6: The `->`, `this`, and `=` operators
  - The `->` operator
  - The `this` pointer
  - Overloading `=`

See “**extras**” section of today's lectures for more examples of classes and overloading (points, dates, complex numbers); Code for these is in the [Week08/extras/](#) folder on the repository/website.

*These slides do not include all issues concerning operator overloading. Among the topics omitted are:*

- ▶ overloading the unary `++` and `--` operators. There are complications because they work in both prefix and postfix form.
- ▶ Overloading the ternary operator: `? :`
- ▶ **Important:** overloading the `[]` operator.

## Usual reminders...

	Mon	Tue	Wed	Thu	Fri
9 – 10		LECTURE	X		
10 – 11		LAB			
11 – 12					
12 – 1					
1 – 2		LAB			
2 – 3					
3 – 4					
4 – 5			LECTURE		

1. Two recorded classes this week: Tuesday at 09.00, and Wednesday at 16.00.
2. **Lab times: Tuesday 10.00-10:50, and 13.00-13.50.** You should try to attend at least one of these.

CS319 – Week 8  
Week 8: Linear Systems, and Operator Overloading

Start of ...

# PART 1: Solving Linear Systems (again)

This continues from where we left off in Week 7

## Part 1: Solving Linear Systems (again)

Our eventual goal is to solve systems of  $N$  simultaneous equations in  $N$  unknowns: *find*  $x_1, x_2, \dots, x_N$ , *such that*

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1N}x_N &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2N}x_N &= b_2 \\ &\vdots \\ a_{N1}x_1 + a_{N2}x_2 + \cdots + a_{NN}x_N &= b_N. \end{aligned}$$

We expressed this as a matrix-vector equation: *Find*  $\mathbf{x}$  *such that*

$$A\mathbf{x} = \mathbf{b},$$

where  $A$  is a  $N \times N$  matrix, and  $\mathbf{b}$  and  $\mathbf{x}$  are (column) vector with  $N$  entries.

We could do this with **Gaussian Elimination** (or  $LU$ -factorization, etc). But instead we use a method that is easier to program: *Jacobi's method*.

The idea is to choose an initial “guess”, which call  $\mathbf{x}^{(0)}$ .

The we try to compute an improved guess, called call  $\mathbf{x}^{(1)}$ .

And we improve that again, to get  $\mathbf{x}^{(2)}$ .

Eventually, we have a sequence of estimates

$$\{\mathbf{x}^{(0)}, \mathbf{x}^{(1)}, \mathbf{x}^{(2)}, \mathbf{x}^{(3)}, \dots, \mathbf{x}^{(k)}, \dots\}$$

If could do this an infinite number of times, then

$$\text{as } k \rightarrow \infty, \text{ we get } \mathbf{x}^{(k)} \rightarrow \mathbf{x}.$$

But in practice, we just iterate until  $\mathbf{x}^{(k)}$  is “close enough” to  $\mathbf{x}$ .

The algorithm (i.e., the method of “improving” the  $\mathbf{x}^{(k)}$ ) comes from the observation that, since (for example)

$$a_{11}x_1 + a_{12}x_2 + \cdots + a_{1N}x_N = b_1,$$

then

$$x_1 = \frac{1}{a_{11}}(b_1 - a_{12}x_2 - a_{13}x_3 - \cdots - a_{1N}x_N)$$

So we can be optimistic that if  $x_2^{(k)}$ ,  $x_3^{(k)}$ ,  $\dots$ ,  $x_N^{(k)}$  are a good estimates for  $x_2$ ,  $x_3$ ,  $\dots$ ,  $x_N$ , then

$$x_1^{(k+1)} = \frac{1}{a_{11}}(b_1 - a_{12}x_2^{(k)} - a_{13}x_3^{(k)} - \cdots - a_{1N}x_N^{(k)})$$

will be an even better one for  $x_1$ .

Applying the same idea to the rest of the equations, we get

$$\begin{aligned}x_1^{(k+1)} &= \frac{1}{a_{11}}(b_1 - a_{12}x_2^{(k)} - a_{13}x_3^{(k)} - \dots - a_{1N}x_N^{(k)}) \\x_2^{(k+1)} &= \frac{1}{a_{22}}(b_2 - a_{21}x_1^{(k)} - a_{23}x_3^{(k)} - \dots - a_{2N}x_N^{(k)}) \\&\vdots \\x_N^{(k+1)} &= \frac{1}{a_{NN}}(b_N - a_{N,1}x_1^{(k)} - \dots - a_{N,N-1}x_{N-1}^{(k)})\end{aligned}$$

This can be programmed with two (or so) nested `for` loops (which is the topic of Lab 6). But it can also be expressed in a simple way, using matrices and vectors.

**See video or annotated slides**

**See video or annotated slides**

Now that we know the method, let us summarise the steps, so as to work out what standard operations on vectors and matrices we need.

We expressed the problem as a matrix-vector equation: *Find  $\mathbf{x}$  such that*

$$A\mathbf{x} = \mathbf{b},$$

*where  $A$  is a  $N \times N$  matrix, and  $\mathbf{b}$  and  $\mathbf{x}$  are (column) vector with  $N$  entries.*

We then derived **Jacobi's method**: choose  $\mathbf{x}^{(0)}$  and set

$$\mathbf{x}^{(k+1)} = D^{-1}(\mathbf{b} + T\mathbf{x}^{(k)}).$$

where  $D = \text{diag}(A)$  and  $T = D - A$ .

Looking at this we see that the fundamental operations are: **vector addition** and **matrix-vector multiplication**.

**PART 2: A matrix class**

## Part 2: A matrix class

Since we already have `Vector` class from last week, our next step is to write a `class` implementation for a `matrix`, along with the associated functions.

Then we need to define a function to multiply a matrix by vector.

First though, we consider the matrix representation. The most natural approach might seem to be to construct a two dimensional array. This can be done as follows (see Lab 4):

```
double **entries = new double *[N];
for (int i=0; i<N; i++)
    entries[i] = new double N;
```

A simpler, faster approach is to store the  $N^2$  entries of the matrix in a single, one-dimensional, array of length  $N^2$ , and then take care how the access is done:

## Part 2: A matrix class

### Matrix.h

```
2 // File: Matrix.h (W07.1)
// Author: Niall Madden (NUI Galway) Niall.Madden@NUIGalway.ie
// Date: Week of 2021-CS319)
4 // What: Implementation of "Matrix": a class of square matrices
// See also: Matrix.cpp and O2TestMatrix.cpp

class Matrix {
8 private:
    double *entries;
10    unsigned int N;
public:
12    Matrix (unsigned int Size=2);
    ~Matrix(void) { delete [] entries; };

    unsigned int size(void) {return (N);};
16    double getij (unsigned int i, unsigned int j);
    void setij (unsigned int i, unsigned int j, double x);

    void print(void);
20 };
```

## Part 2: A matrix class

from Matrix.cpp

```
Matrix::Matrix (unsigned int Size)
10 {
    N = Size;
12   entries = new double [N*N];
}

void Matrix::setij (unsigned int i, unsigned int j, double x)
16 {
    if (i<N && j<N)
18     entries[i*N+j]=x;
    else
20     std::cerr << "Matrix::setij(): Index out of bounds."
                << std::endl;
22 }
```

## Part 2: A matrix class

from Matrix.cpp

```
24 double Matrix::getij (unsigned int i, unsigned int j)
   {
26     if (i<N && j<N)
           return(entries[i*N+j]);
28     else
           {
30         std::cerr << "Matrix::getij(): Index out of bounds."
                       << std::endl;
32         return(0);
           }
34 }

36 void Matrix::print (void)
   {
38     // std::cout << "Matrix is of size " << M << "-by-"
   // << N << std::endl;
40     for (unsigned int i=0; i<N; i++)
           {
42         for (unsigned int j=0; j<N; j++)
               std::cout << "[" << entries[i*N+j] << "];"
44         std::cout << std::endl;
           }
}
```

We'll test this by implementing matrix-vector multiplication function:

### O2TestMatrix.cpp

```
2 // File:      01TestMatrix.h (Set v=A*u)
// Author:    Niall Madden (Niall.Madden@NUIGalway.ie)
// Date:      Week 8 of 2021-CS319)
4 // What:     Test the implementation Matrix class

48 void MatVec(Matrix &A, Vector &u, Vector &v)
   {
50     unsigned int N;
       N = A.size();
52     if ( (N != u.size()) || ( N != v.size() ) )
           std::cerr << "dimension_mismatch_in_MatVec_" << std::endl;
54     else
           for (unsigned int i=0; i<N; i++)
56         {
               double x=0;
58             for (unsigned int j=0; j<N; j++)
                   x += A.getij(i,j)*u.geti(j);
60             v.seti(i,x);
           }
62 }
```

**PART 3: Coding Jacobi's Method**

## Part 3: Coding Jacobi's method

Now we can implement Jacobi's method. The specific example coded, we will solve  $N = 3$  equations whose matrix representation is

$$9x_1 + 3x_2 + 3x_3 = 15 \quad (1)$$

$$3x_1 + 9x_2 + 3x_3 = 15 \quad (2)$$

$$3x_1 + 3x_2 + 9x_3 = 15 \quad (3)$$

This problem is constructed so that the solution is  $x_1 = x_2 = x_3 = 1$ .

Have a look at the [main\(\)](#) function in [03Jacobi.cpp](#) to see how the problem is set up, and how the Jacobi solver is called. Here we will focus on that solver.

## Part 3: Coding Jacobi's method

See 02Jacobi.cpp for more details

```
100 // Use Jacobi's method to solve Ax=b,  
101 // On entry : x is the initial guess  
102 // On exit : x is the estimate for the solution  
103 void Jacobi(Matrix &A, Vector &b, Vector &x,  
104             unsigned int &count, double tol)  
105 {  
106     unsigned int N=A.size();  
107     count=0;  
108     if ( (N != b.size()) || (N != x.size()) )  
109         std::cout << "Jacobi: error - A must be the same size as b,x"  
110                 << std::endl;
```

## Part 3: Coding Jacobi's method

See 02Jacobi.cpp for more details

```
112 Matrix Dinv(N), T(N);    // The diagonal and off-diagonal matrices
113 for (unsigned int i=0; i<N; i++)
114     for (unsigned int j=0; j<N; j++)
115         if (j != i)
116             {
117                 T.setij(i,j, -A.getij(i,j));
118                 Dinv.setij(i,j,0.0);
119             }
120     else
121     {
122         T.setij(i,j, 0.0);
123         Dinv.setij(i,j, 1.0/A.getij(i,j));
124     }
```

## Part 3: Coding Jacobi's method

See 02Jacobi.cpp for more details

```
126 // Now implement the algorithm:
    Vector d(N), r(N);
128 do
    {
130     count++;
        MatVec(T,x,d); // Set d=T*x
132     VecAdd(d, b, d); // set d=b+d (so d=b+T*x)
        MatVec(Dinv, d, x); // set x = inverse(D)*(b+T*x)

        MatVec(A, x, r); // set r=A*x
136     VecAdd(r, b, r, 1.0, -1.0); // set r=b-A*x
138 } while ( r.norm() > tol);
```

.....

Of course, the above code would be a lot neater, and much more readable, if we were able to write, for example, `r=A*x` instead of `MatVec(A,x,r)` ....

**Exercise (8.1)**

Write a method `Matrix::norm()` that returns the “Entry-wise” 2-norm of a matrix (also called the **Frobenius** or Hilbert–Schmidt norm) :

$$\|A\|_p = \left( \sum_{i=1}^n \sum_{j=1}^n |A_{i,j}|^p \right)^{1/p}.$$

and the max-norm:

$$\|A\|_0 = \max_{i,j} |A_{i,j}|.$$

CS319 – Week 8  
Week 8: Linear Systems, and Operator Overloading

Start of ...

# PART 4: Copy Constructors

In the next section, we will introduce the idea of **Operator Overloading**. But to get this to work, we need to study **copy constructors**.

This is a very technical area of C++ programming, but is unavoidable.

As we already know, **constructor** is a method associated with a class that is called automatically whenever an object of that class is declared.

But there are time when objects are *implicitly* declared, such as when passed (by value) to a function.

Since this will happen often, we need to write special constructors to handle it.

Last week we defined a class for vectors:

- ▶ It stores a vector of  $N$  doubles in a dynamically assigned array called *entries*;
- ▶ The constructor takes care of the memory allocation.

```
2 // From Vector.h (Week 7)
3 class Vector {
4     private:
5         double *entries;
6         unsigned int N;
7     public:
8         Vector (unsigned int Size=2);
9         ~Vector(void);
10
11         unsigned int size(void) {return N;};
12         double geti (unsigned int i);
13         void seti (unsigned int i, double x);
14         // print(), zero() and norm() not shown
15 };
16
17 // Code for the constructor from Vector.cpp
18 Vector::Vector (unsigned int Size) {
19     N = Size;
20     entries = new double[Size];
21 }
```

We then wrote some functions that manipulate vectors, such as `AddVec` in `Week07/01TestVector.cpp`

```
1 void VecAdd (Vector &c, Vector &a, Vector &b,  
2             double alpha=1.0, double beta=1.0);
```

Note that the `Vector` arguments are passed by reference...

What would happen if we tried the following, seemingly reasonable piece of code?

```
Vector a(4);  
a.zero(); // sets entries of a all to 0  
Vector c=a; // should define a new vector, with a copy of a
```

This will cause problems for the following reasons:

To solve this problem, we should define our own **copy constructor**. A **copy constructor** is used to make an exact copy of an existing object. Therefore, it takes a single parameter: the address of the object to copy. For example:

See `Vector08.cpp` for more details

```
20 // copy constructor (Version W08.1)
21 // Class definition in Vector08.h has also changed
22 Vector::Vector (const Vector &old_Vector)
23 {
24     N = old_Vector.N;
25     entries = new double[N];
26     for (unsigned int i=0; i<N; i++)
27         entries[i] = old_Vector.entries[i];
28 }
```

The **copy constructor** can be called two ways:

(a) *explicitly*, .e.g,

```
Vector V(2);  
V.seti(0)=1.0; V.seti(1)=2.0;  
Vector W(V); // W is a copy V
```

(b) *implicitly*, when ever an object is passed by value to a function. If we have not defined our own copy constructor, the default one is used, which usually causes trouble.

**CS319 – Week 8**  
**Week 8: Linear Systems, and Operator Overloading**

**END OF PART Part 4**

CS319 – Week 8  
Week 8: Linear Systems, and Operator Overloading

Start of ...

# PART 5: Operator Overloading

Recall that, along with **Encapsulation** (Classes) and **Inheritance** (deriving new classes from old), **Polymorphism** is one of the pillar ideas of Object-Oriented Programming

So far we have seen two forms of **Polymorphism**:

- (a) we may have two functions with the same name but different argument lists. This is **function overloading**.
- (b) **templates** allow us to define a function or class that with arbitrary data-types, which are not specified until used. In the case of a **class template** it is specified when an object of that class is defined.

We'll cover another form of polymorphism today: **“Operator overloading”** .

Our main goal is to overload the addition (+) and subtraction (-) operators for vectors.

Last week, we wrote a function to add two **Vectors**: `AddVec`.

It is called as `AddVec(c, a, b)`, and adds the contents of vectors `a` and `b`, and stores the result in `c`.

It would be much more natural to redefine the standard **addition** and **assignment** operators so that we could just write `c=a+b`. This is called **operator overloading**.

To overload an operator we create an **operator function** – usually as a member of the class. (It is also possible to declare an operator function to be a **friend** of a class – it is not a member but does have access to private members of the class. More about **friends** later).

The general form of the operator function is:

```
return-type class-name::operator#(arguments)  
{  
    :    // operations to be performed.  
};
```

*return-type* of a operator is usually the class for which it is defined, but it can be any type.

Note that we have a new key-word: `operator`. The operator being overloaded is substituted for `#`

Almost all C++ operators can be overloaded:

+	-	*	/	%	^	&		~	!
=	<	>	+=	-=	*=	/=	%=	^=	&=
=	<<	>>	>>=	<<=	==	!=	<=	>=	&&
	++	--	->*	,	->	[]	()	new	delete

but not . :: .\* ?

- ▶ Operator precedence cannot be changed: `*` is still evaluated before `+`
- ▶ The number of arguments that the operator takes cannot be changed, e.g., the `++` operator will still take a single argument, and the `/` operator will still take two.
- ▶ The original meaning of an operator is not changed; its functionality is extended. It follows from this that operator overloading is always relative to a user-defined type (in our examples, a `class`), and not a built-in type such as `int` or `char`.
- ▶ Operator overloading is always relative to a user-defined type (in our examples, a `class`).
- ▶ The assignment operator, `=`, is automatically overloaded, but in a way that usually fails except for very simple classes.

We are free to have the overloaded operator perform any operation we wish, but it is good practice to relate it to a task based on the traditional meaning of the operator. E.g., if we wanted to use an operator to add two matrices, it makes more sense to use `+` as the operator rather than, say, `*`.

We will concentrate mainly on binary operators, but later we will also look at overloading the unary “minus” operator.

.....

For our first example, we'll see how to overload `operator+` to add two objects from our `vector` class.

First we'll add the declaration of the operator to the class definition in the header file, `Vector08.h`:

```
vector operator+(vector b);
```

Then to `Vector08.cpp`, we add the code

See `Vector08.cpp` for more details

```
95 // Overload the + operator.
96 Vector Vector::operator+(Vector b)
97 {
98     Vector c(N); // Make c the size of a
99     if (N != b.N)
100         std::cerr << "vector::+ : cant add two vectors of different size!"
101                 << std::endl;
102     else
103         for (unsigned int i=0; i<N; i++)
104             c.entries[i] = entries[i] + b.entries[i];
105     return(c);
106 }
```

First thing to notice is that, although `+` is a binary operator, it seems to take only one argument. This is because, when we call the operator, `c = a + b` then `a` is passed **implicitly** to the function and `b` is passed **explicitly**. Therefore, for example, `a.N` is known to the function simply as `N`.

The temporary object `c` is used inside the object to store the result. It is this object that is returned. Neither `a` or `b` are modified.

**CS319 – Week 8**  
**Week 8: Linear Systems, and Operator Overloading**

**END OF PART Part 5**

CS319 – Week 8  
Week 8: Linear Systems, and Operator Overloading

Start of ...

**PART 6: The “pointy”, `this`, and `=` operators**

We now want to see another way of accessing the implicitly passed argument. First, though, we need to learn a little more about pointers, and introduce a new piece of C++ notation.

First, remember that if, for example, `x` is a `double` and `y` is a pointer to `double`, we can set `y=&x`. So now `y` stores the memory address of `x`. We then access the contents of that address using `*y`.

Now suppose that we have an object of type `Vector` called `v`, and a *pointer to vector*, `w`. That is, we have defined

```
Vector v;  
Vector *w;
```

Then we can set `w=&v`. Now accessing the member `N` using `v.N`, will be the same as accessing it as `(*w).N`.

It is important to realise that `(*w).N` is **not** the same as `*w.N`.

However, C++ provides a new operator for this situation: `w->N`, which is equivalent to `(*w).N`.

When writing code for functions, and especially overloaded operators, it can be useful to **explicitly** access the implicitly passed object.

That is done using the `this` pointer, which is a pointer to the object itself.

.....

As we've just noted, since `this` is a pointer, its members are accessed using either `(*this).N` or `this->N`.

The following simple (but contrived ) demonstration shows why we might like to use the `this` pointer.

The (original) constructor for our `Vector` class took an `integer` argument called `Size`:

```
// Original version
Vector::Vector (unsigned int Size)
{
    N = Size;
    entries = new double[Size];
}
```

Suppose, for no good reason, we wanted to call the passed argument `N`: Then we would get the code below:

```
// Silly, broken version
Vector::Vector (unsigned int N)
{
    N = N;
    entries = new double[N];
}
```

Surprisingly, this will compile, but will give bizarre results (before crashing). To get around this we must distinguish between the local, passed, variable `N`, and the class member `N`.

This can be done by changing the offending line to:

```
this->N = N;
```

A much better use of this is for the case where a function must return the address of the argument that was passed to it. This is the case of the assignment operator.

See `Vector08.cpp` for more details

```
100 // Overload the = operator.
    Vector &Vector::operator=(const Vector &b)
    {
102     if (this == &b)
        return(*this); // Taking care for self-assignment

        delete [] entries; // In case memory was already allocated

        N = b.N;
108     entries = new double[b.N];
        for (unsigned int i=0; i<N; i++)
110         entries[i] = b.entries[i];

112     return(*this);
    }
```
