**Lecture 22: 1st Order Differential Equations  
(Part II)**

Monday 24<sup>th</sup> Nov 2008

## Topics of the day...

- 1 Recall: 1st Order Differential Equations
- 2 Recall: Separable Equations
- 3 Recall: Homogeneous Functions
- 4 Solving homogeneous DEs
- 5 First Order Linear Differential Equations
- 6 Integrating Factors
  - Technique
  - Examples

See also Sections 9.3 and 9.5 of Stewart.

## Recall: 1st Order Differential Equations

Last Wednesday, we started a new section on solving 1st order differential equations.

$$y'(x) = f(x, y).$$

## Recall: Separable Equations

A first order equation  $\frac{dy}{dx} = f(x, y)$  is **separable** if we can write  $f(x, y)$  as the product of some functions  $g(x)$  and  $h(y)$ . That is, it has the form

$$\frac{dy}{dx} = g(x)h(y).$$

Such an equation can be solved by writing

$$\frac{1}{h(y)} dy = g(x) dx$$

and integrating both sides:

$$\int \frac{1}{h(y)} dy = \int g(x) dx$$

## Recall: Homogeneous Functions

Last Wednesday we also saw that a function  $f(x, y)$  is **homogeneous of degree  $k$**  if for every real number  $t$  we have

$$f(tx, ty) = t^k f(x, y).$$

In interest to us is if right-hand side of the differential equation  $y'(x) = f(x, y)$  is *homogeneous of degree 0*.

Then we can make the equation *separable* with the substitution  $v = \frac{y}{x}$ .

## Solving homogeneous DEs

Given a first order differential equation  $\frac{dy}{dx} = f(x, y)$  where  $f(x, y)$  is *homogeneous of degree 0*,

1 Let  $v = \frac{y}{x}$  and find the function  $h$  such that  $h(v) = f(x, y)$ .

2 Because we have  $y = vx$ , differentiate to get:  $\frac{dy}{dx} = v + x \frac{dv}{dx}$

3 Substitute into the original differential equation:

$$v + x \frac{dv}{dx} = h(v).$$

4 This equation involving  $v$  and  $x$  is separable:

$$\frac{1}{h(v) - v} dv = \frac{1}{x} dx$$

5 Solve it in the same way we solve the separable problems from last week.

### Example

Solve the equation  $\frac{dy}{dx} = \frac{xy + y^2}{x^2}$ .

## Solving homogeneous DEs

### Example

Solve the following initial value problem:

$$\frac{dy}{dx} = \frac{x^2 + xy}{xy + y^2}, \quad y(2) = 1.$$

## Solving homogeneous DEs

### Example (Autumn exam 07/08, Q4(iii))

Solve the following differential equation:

$$2xy \frac{dy}{dx} = x^2 + y^2, \quad y(2) = 2.$$

## Solving homogeneous DEs

### Exercise (22.1)

Find the general solution to the following differential equations:

$$1 \quad \frac{dy}{dx} = \frac{x+y}{x-y}.$$

$$2 \quad \frac{dy}{dx} = \frac{xy}{x^2 + 2y^2}.$$

### Exercise (22.2)

Solve the following initial value problems:

$$1 \quad \frac{dy}{dx} = \frac{x^2 + xy + y^2}{x^2}; \quad y(1) = 1.$$

$$2 \quad \frac{dy}{dx} = \frac{x^3 + 3xy^2}{3x^2y + y^3}; \quad y(1) = -1$$

# First Order Linear Differential Equations

To finish the course, we'll look at ways of solving *first order linear* differential equation such as:

$$\frac{dy}{dx} + P(x)y = Q(x).$$

This is called *Linear* because the only expression for  $y$  is linear.

## Example

These are linear equations:

- $\frac{dy}{dx} - 3y = e^x.$
- $x\frac{dy}{dx} + y = \sin(x).$
- $\frac{dy}{dx} + \sqrt{xy} = \ln(x).$

These are **not** linear:

- $\frac{dy}{dx} - y^3 = e^x.$
- $y\frac{dy}{dx} = \sin(x).$
- $\frac{dy}{dx} + x\sqrt{y} = \ln(x).$

# First Order Linear Differential Equations

A general strategy for solving such an equation is to multiply the equation by some expression  $v(x)$  that simplifies the problem.

Then we get:

$$v(x) \frac{dy}{dx} + v(x)P(x)y = v(x)Q(x).$$

The idea is to choose  $v(x)$  so that the left hand side of the above equation is the derivative of the product  $vy$ . This would require

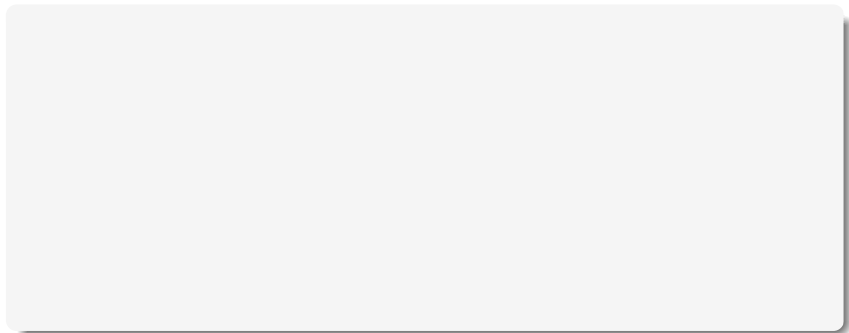

$$v \frac{dy}{dx} + vP(x)y = v \frac{dy}{dx} + y \frac{dv}{dx},$$

that is

$$vP(x)y = y \frac{dv}{dx} \implies \frac{dv}{dx} = vP(x).$$

## Integrating Factors

So we need to choose  $v$  so that  $\frac{dv}{dx} = vP(x)$ . This means:

The expression  $v(x)$  is called an *integrating factor* for the differential equation.

## Example

Solve the differential equation  $y' - 3y = e^x$ .

## Summary of Technique of Integrating Factors

Given a problem of the form:

$$\frac{dy}{dx} + P(x)y = Q(x).$$

- 1 Let  $v = e^{\int P(x)dx}$ .
- 2 Solve  $(vy)' = vQ(x)$  by integrating:

$$vy = \int vQ(x)dx.$$

not forgetting the constant of integration.

- 3 Divide by  $v$  to get the solution:

$$y = \frac{\int vQ(x)dx}{v}.$$

**Example**

Solve the equation

$$x \frac{dy}{dx} + y = \sin(x)$$

subject to the initial condition  $y(\pi/2) = 1$ .

**Example**

Solve the equation

$$x \frac{dy}{dx} - y = x^3, \quad y(1) = 1.$$

**Example (Q3(c), Semester 1, '06/'07)**

$$e^x \frac{dy}{dx} + 2e^x y = 1.$$

**Example**

Solve the following differential equation:

$$\frac{dy}{dx} + \cos(x)y = 2xe^{-\sin(x)}.$$

**Exercise**

Solve the following differential equations:

(i)  $\frac{dy}{dx} + \frac{y}{x} = x^2 - \frac{1}{x}, \quad y(1) = 1/4.$

(ii)  $\frac{dy}{dx} + 2y = e^{-x}.$

(iii)  $y' = x^2 + x^2y$

(iv)  $y' + 3xy = x$

(v)  $\frac{dy}{dx} = \sin(x)y = 3 \sin(2x)$

(vi)  $xy' + y = 2x \sin(x)$

(vii)  $2xyy' = x^2 + 3y^2$

(viii)  $\frac{dy}{dx} + \frac{y}{\tan(x)} = 3x + 1$
